Abstract—Among different mechanical drives of industrial application harmonic drive mechanisms (HDM) are distinguished by minimal materials consumption and overall dimensions, provide high efficiency, torsion rigidity and low kinematic error. Due to this they are widely used in mechanical actuators, robotics, aerial drives, supporting and turning arrangements of follow-up systems, dial indicators and other precise mechanisms. Drive designs based on internal and external gearing wave generating are considered, many of them are produced at the state-of-the-art level and implemented in many batch production servos.

Index Terms—harmonic drive, wave generator, torsion rigidity, kinematic error

I. INTRODUCTION

Instrument and special mechanical engineering industry requires minimal dimensions and mass of follow-up low-inertia mechanical drives for mobile devices. Multi-stage gearing drives (gear ration up to 100000 and higher) are used to reduce electrical motor high rpm (from above 10000 rpm). In these drives lesser number of reducer stages is possible due to implementation of drives distinguished by high quality characteristics of loading capability, kinematic error and efficiency. Harmonic drives are among the best in terms of these criteria [1-18]. This type drive principle of operation is based on the engagement of rigid and deformable flexible gear wheels. Deformation process is provided by wave generator. Flexible wheel is a ring or a thin shell. Variety of flexible gear geometry provides different designs of the drive which comply with different requirements in terms of configuration, motion transmission to any closed space without using any sealing units, etc. Wave generator may be positioned inside or outside relatively to the flexible wheel and deform it in one or several zones. Gear ratio of a single stage harmonic drive having steel flexible wheel ranges from 60 to 600. It provides multi-pair engagement. Total amount of teeth engaged is up to 40%. There is no engagement backlash, kinematic error decreases, efficiency and loading capability are high [1-4, 6, 8-12, 16, 17]. All this predetermines the usage of harmonic drive as the output stage of a gear train. It is also characterized by low vibration and noise [5, 13, 18].

II. GEOMETRICAL CALCULATION OF HARMONIC DRIVES

Harmonic drive geometry design and computational theory is created at Theory of Machines and Mechanisms dept. of BMSTU and is based on theory of geometry analysis of involute engagement developed by V.A. Gavrilenko and his disciples research of HDM [6, 11-13, 15-18], other proceedings.

This theory is based on the assumption that wave generator of the drive provides constant radius of curvature of deformed flexible wheel mean line within the area of engagement marked by central angle 2β in Fig. 1, a, b. Outside these areas flexible wheel has natural/loose form of deformation. Within constant radius of curvature area harmonic drive engagement is considered as internal involute engagement of rigid wheel (number of teeth is \( z_r \)) and conditional wheel which number of teeth \( z_c \) is calculated.

Figure 1. Harmonic drive engagement diagram: a – outside deformation, b – inside deformation by the wave generator

Manuscript received July 21, 2019; revised April 1, 2020.
Calculated number of teeth is:
\[
z_c = \frac{z_f}{1 \pm \frac{k_f}{w_0 \cdot r_{soft}}},
\]
where \(w_0\) – radial deformation along major axis, \(r_{soft}\) – mean radius of the flexible wheel; \(k_f = \frac{r}{\lambda-B}\) - coefficient depending of the angle of wheel generator cover;
\[
A = \frac{\pi}{2} - \beta - \sin \beta \cdot \cos \beta;
\]
\[
B = \frac{4\beta}{\pi} \cdot \sin \beta + \frac{4}{\pi} \cdot \cos \beta - 2 \sin \beta,
\]
where \(\beta\) – angular coordinate of the constant radius of curvature area \((35 \leq \beta \leq 65^\circ)\).

The main input parameters for geometry characteristics calculation are: \(U\) – gear ratio of the drive; type of deformation (inside/outside); \(f_{z}, r_{z}\) – flexible and rigid wheels numbers of teeth; \(T, T_{max}\) – rated and maximal torques at the output drive shaft; \(n_h\) – rpm of the wave generator shaft; \(l_h\) – service life of the drive; \(\psi_{ring}\) – flexible wheel gear teeth tip width coefficient; flexible wheel strength parameters – hardness (HRC), endurance strength \((\sigma_f)\) of the material, torsion rigidity coefficient \((C, \text{optional parameter})\) [15].

The greater flexible wheel diameter the greater torsion rigidity and the less kinematic error. As the wheel diameter depends on the transmitted torque gear ratio of HDM should be the greatest providing compliance with overall dimensions of the unit.

Design calculation implies obtaining diameter \(d_{soft}\) of the flexible wheel mean surface in non-deformed state in accordance with the following conditions:

1) Flexible wheel bending strength [13]:
\[
d_{soft} = 220 \cdot \sqrt{k_{d} \cdot k_{el} \cdot \frac{h_{wd}}{d_{soft}} \left( k_{c} - \frac{u}{u+1} \right) \cdot T},
\]
where \(k_{d}\) - dynamism coefficient;
\(k_{el}\) - overload coefficient;
\(k_{c}\) - deformation form coefficient;
\(\frac{h_{wd}}{d_{soft}}\) - flexible wheel relative thickness below teeth tip;
\(T\) - Endurance calculation:
\[
d_{soft} = 16 \cdot \sqrt{T} \cdot \sqrt{\frac{1}{(0.03 \cdot U - 1)} \cdot \sigma_{f0}}.
\]

2) Torque rigidity coefficient:
\[
d_{soft} = \left( 1.12 - \frac{\sqrt{\beta}}{8000} \right) \cdot c^{(0.34+\gamma_{m})}.
\]

The greatest among these diameters is the basis for engagement module pitch calculation which is rounded up to the closest standard value \(m\):
\[
m' = \frac{d_{soft}}{z_f}.
\]

Module pitch may be readjusted.
Pitch diameters of the wheels are:
\[
d_f = m \cdot z_f;
\]
\[
d_r = m \cdot z_r.
\]

Flexible wheel rim thickness below the tooth tip:
\[
h_{wd} = \left( \frac{10.6 \cdot T \cdot 10^3}{\sigma_{f0} d_f} + 0.007 \right) \cdot d_f,
\]
but not greater than \(0.018 \cdot d_f\).

The main variable parameter is relative radial deformation of the flexible wheel:
\[
\frac{w_{h}}{r_{soft}} = \left( \frac{z_r - z_f}{z_f} \right) \cdot \gamma,
\]
where \(\gamma = 0.9...1.2\) - coefficient of relative radial deformation.

The first expression as all the rest, containing dual arithmetic signs, is combined. The upper sign relates to inner deformation of flexible wheel by disk or cam wave generator, the lower sign – to outer deformation by ring-shaped generator.

Modification factor of the basic rack is:
\[
x_{f} = \left( h_{c} + c + \frac{h_{wd}}{2m} \right) \cdot \delta,
\]
where \(\delta\) - coefficient of modification factor deviation.

Based on the diagram of wave engagement the radius of deformed flexible wheel mean line may be presented as
\[
r_{wd} = m' \left( \frac{z_f}{2} + h_{c} + c + \frac{h_{wd}}{2m} + x_{f} \right).
\]

\(\delta\) and \(\gamma\) are variable parameters and are assigned as:
\(\delta = 1,0...1.4\), \(\gamma = 0.9...1.2\) - for inside deformation,
\(\delta = 0.8...1.1\), \(\gamma = 0.8...1.2\) - for outside deformation.

Quality of engagement may be improved considering possible ranges of input values. Goal function in this process is contact ratio coefficient.
III. INDUSTRIAL HARMONIC DRIVES SAMPLES

Geometry calculation algorithm is presented in [12, 13] and is applicable to HDM which gear ratio ranges from 60 to 100000. Principle schemes of these HDMs of inside and outside deformation are presented in [15].

Given below are some industrially implemented designs of drives based on HDM which geometry and kinematic characteristics were obtained based on the developed algorithm.

A. Two-stage Gear Transmission Power Drive

![Figure 2. Two-stage gear transmission power drive](image)

Fig. 2 presents the design of power drive based on two-stage harmonic drive. For unification purpose geometry parameters of gear engagement are the same: gear ratio is 60 or 80; module pitch is 0.4 or 0.3; total gear ratio is 4500 or 13000. Relatively to known designs overall dimensions of the drive developed are 14% less due to usage of narrow flexible wheel of intermediate stage and positioning supporting bearings of the output shaft inside flexible wheel.

| TABLE I. TECHNICAL CHARACTERISTICS OF TWO-STAGE GEAR TRANSMISSION POWER DRIVE |
|---------------------------------|--------|----------------|----------|----------|
| Output shaft load torque, N·m   | 80     | Efficiency     | 0.57     |
| Angular error of the output shaft at rated load, not greater than | 0.0005 |
| Power source voltage, V         | 27 ± 2 |
| Power consumption, Wt           | 18     |
| Overall dimensions, mm          | 70×120×140 |
| Mass, kg                        | 2.5    |

B. High-torque Drive

![Figure 3. High-torque drive](image)

Fig. 3 presents output stage of power train designed for high-torque drives of automated control. Three-disk wave generator is implemented in this design. In comparison with two-disk wave generator this design excludes sideway of the flexible wheel, twisting of its end cross-sections that improves mesh of the harmonic drive teeth.

| TABLE II. TECHNICAL CHARACTERISTICS OF HIGH-TORQUE DRIVE |
|---------------------------------|--------|----------------|----------|----------|
| Output shaft torque, kN·m        | 80     | Efficiency     | 0.63     |
| Overall dimensions, mm           | 800×800×1000 |
| Mass, kg                        | 2880   |
| Gear ratio:                      |        |
| harmonic drive stage             | 120    |
| total                            | 18 000 |

C. Discrete Positioning Electromechanical Drive

![Figure 4. Discrete positioning electromechanical drive](image)

The design of discrete positioning electromechanical drive based on HDM, presented in Fig. 4, provides new functional possibilities for transmitting continuous electrical motor shaft rotation to discrete translational motion of the output link of servo mechanism. This is three-stage drive. The first stage is cylindrical gearing of outer engagement, the second – combined harmonic drive providing discrete motion, the third, output one, is screw-and-nut drive.

Introduction of discrete motion harmonic drive decreased production cost of a single unit by 40% due to the 2.5 times decrease of the number of parts, metal
consumption decrease (3 times) and production labor intensity reduction.

**TABLE III. TECHNICAL CHARACTERISTICS OF TWO-STAGE GEAR TRANSMISSION POWER DRIVE**

Significant variety of different drive designs is presented in scientific report [12].

### IV. CONCLUSION

In some cases harmonic gear drive has no competitors. It’s also clear that new HDM designs and rigid wheel gear trains are no rivals, both contribute to new decisions. HDM has some shortcomings: inability to provide low gear ratio (less than 50), rather high losses at idle, it is sensitive to lubrication and types of lubricants.

Nevertheless, the area of HDM will broaden, enriching modern servo engineering.

Gennady A. Timofeev was born in Armavir, Soviet Union, at 01.02.1948. He gained his university degree in field of wheeled cars in Moscow high technical School, Soviet Union in 1967, PhD degree in field of harmonic drives with external deformation in 1974, habilitated in 1996 in IMASH RAN, Moscow, Russia.

He worked at Moscow high technical School (now Bauman Moscow State Technical university) since graduation as engineer, lecturer and later as professor. Now he is a head of Robotics and Complex automation department. His scientific interests lays in field of automated design of machines.

Prof. Timofeev is a member of Russian association of technical universities, member of IFToMM, he has been awarded with State prize of Russian Federation in field of education and science in 2008.

Andrew V. Yaminski was born in Moscow, Soviet Union, at 07.01.1953. He gained his university degree in field of aircraft engines in Moscow high technical School, Soviet Union in 1976, PhD degree in field of thermocumlar synthesis in 1983.

He worked at Moscow high technical School (now Bauman Moscow State Technical university) since graduation as engineer, lecturer and later as associated professor. His scientific interests lays in field of engineering education.

Prof. Yaminski is a member of Russian journalist association, he has been awarded with several government award from ministry of science and education of Russia.

Yuri V. Kostikov was born in Moscow, Soviet Union, at 01.01.1947. He gained his PhD degree in field of harmonic drives in Bauman Moscow High technical school, Moscow, Soviet Union. He worked at Moscow high technical School (now Bauman Moscow State Technical university) since 1973. His scientific interests lays in field of Harmonic drives design. Prof. Kostikov is a renown engineer, he was awarded 3 VDNKh silver medals for is inventions.

Eugene O. Podchasov was born in Moscow, Russia, at 05.02.1994. He gained his bachelor degree in field of metal cutting machines and tools in Bauman Moscow State Technical University in 2013, Master degree in field of Automation of technological processes in 2018.

He worked at Bauman Moscow State technical university as laboratory assistant in 2013-2016. Since 2016 he works as lecturer. His scientific interest lay in field of mechanisms and software design of insulin pumps.

Mr. Podchasov has been awarded with Moscow government prize for best technical project by young researcher in 2010, and by Russian Fund for Promoting Innovations in 2017.
